Abstract

In order to improve the accuracy of gas flowrate measurement by means of the differential pressure flowmeters, it is necessary to apply equations for determination of coefficients of gas flow equation, which would provide the lowest total relative expanded uncertainty of calculation, and to increase the accuracy of input values measurement in real time. One of these values is the arithmetic mean deviation of roughness profile of pipe internal surface. The equation for calculating the arithmetic mean deviation of roughness profile of pipe internal surface in real time was obtained. The equation for calculating the total relative expanded uncertainty of measurement result of arithmetic mean deviation of roughness profile of pipe internal surface in real time and components of this uncertainty were obtained.

Keywords: gas flowrate; roughness; measurement; uncertainty; pipeline parameters.

1. Introduction

Differential pressure method is applied for gas flowrate measurement. The requirements to the differential pressure flowmeters are presented in ISO 5167-1,2,3,4:2003 [1]–[4] and AGA 3-1,2:2003 [5], [6] standards.

Mass gas flowrate according to the differential pressure method is determined by the equation [1]

$$q_m = \frac{C}{\sqrt{1-\beta^4}} \varepsilon \frac{\pi}{4} d^2 \sqrt{2\rho\Delta p}, \quad (1)$$

where C is discharge coefficient; β is diameter ratio of primary device throat; ε is expansion factor of gas; d is diameter of primary device throat under working conditions; ρ is density of gas under working conditions (at absolute gas pressure p and thermodynamic temperature of gas T); Δp is differential pressure across the primary device.

Discharge coefficient is one of basic coefficients of the gas flowrate equation. Each primary device is described by its discharge coefficient. The equations of discharge coefficients are presented in:

- ISO 5167-2:2003 [2] for orifice plate;
- ISO 5167-3:2003 [3] for nozzle, long radius nozzles and Venturi nozzle;
- ISO 5167-4:2003 [4] for Venturi tubes.

Discharge coefficient of each primary device is determined in a certain range of relative roughness of pipe internal surface, which depends on arithmetic mean deviation of roughness profile Ra of pipe internal surface and upstream internal pipe diameter D under working conditions.

The arithmetic mean deviation of the profile Ra is the mean value of the absolute value of the profile departure y within the reference length l (Fig. 1).

Fig. 1. The arithmetic mean deviation of the profile.

The arithmetic mean deviation of the profile Ra is determined by equation [7]

$$Ra = \frac{1}{l} \int_0^l |y(x)| dx = \frac{1}{n} \sum_{i=1}^n |y_i|,$$

where n is number of measurements.

Relative roughness of pipe internal surface is determined as $10^4 \frac{Ra}{D}$. Allowable values of $10^4 \frac{Ra}{D}$ depend on the type of the primary device and are presented in:

- Table 1 and Table 2 of ISO 5167-2:2003 [2] for orifice plate;

Table 4. Upper limits of relative roughness of the upstream pipe for Venturi nozzles.

β	≤ 0.35	0.36	0.38	0.40	0.42	0.44	0.46	0.48	0.50	0.60	0.70	0.775
$10^4 \frac{Ra}{D}$	8.0	5.9	4.3	3.4	2.8	2.4	2.1	1.9	1.8	1.4	1.3	1.2

- according to ISO 5167-4:2003 [4] for each type of Venturi tube the upper limits of relative roughness $10^4 \frac{Ra}{D} = 3,2$ on a length at least equal to $2D$ measured from the upstream end of the entrance cylinder of the Venturi tube.

Differential pressure method cannot be applied when the relative roughness of pipe internal surface does not conform to the maximum and minimum allowable values described above on distance L upstream to primary device ($L \leq 10D$ [2], [3] for orifice plate, any nozzle and $L \leq 2D$ [4] for each type of Venturi tube) or to the first local resistance. Therefore, measurement of arithmetic mean deviation of roughness profile of pipe internal surface in real time is an important problem to be solved.

2. Definition of arithmetic mean deviation of the roughness profile of pipe internal surface in real time

For definition of arithmetic mean deviation of the roughness profile Ra of pipe internal surface in real time the following equations are applied:

- system of differential equations [8]

$$\begin{cases} \frac{dp}{\rho} + \frac{\lambda v^2}{2D} dx = 0; \\ \frac{dm}{d\tau} = q_m = \rho v F = const, \end{cases} \quad (3)$$

where dp is the variation of the gas pressure across elementary pipe section dx upstream of primary device; λ is the hydraulic resistance coefficient of friction of gas on the internal surface of pipe; v is the linear velocity of gas in pipe; dm is the variation of gas mass during the period of time $d\tau$; F is the cross sectional area of pipe;

- Colebrook-White equation [9]

$$\frac{k_s}{D} = \left(3.71 \cdot 10^{-\frac{1}{2\sqrt{\lambda}}} - \frac{9.34}{Re_D \sqrt{\lambda}} \right), \quad (4)$$

where k_s is equivalent roughness of the pipe internal surface.

Solving system of differential equations (3) we obtained pressure distribution p_x along the length x of the pipe, which is determined by the equation

$$p_x = \sqrt{p_1^2 - (p_1^2 - p^2) \frac{x}{L}}, \quad (5)$$

where p_1 is gas pressure at a distance L before primary device; $\bar{\rho}$ is average value of gas density along the length of pipe, which is determined by the gas thermodynamic temperature T and the average value of gas pressure \bar{p} along the length of pipe.

Based on (5) the average value of gas pressure \bar{p} along the length of pipe is determined by the equation

$$\bar{p} = \frac{1}{L} \int_0^L \sqrt{p_1^2 - (p_1^2 - p^2) \frac{x}{L}} dx = \frac{2}{3} \left(p_1 + \frac{p^2}{p_1 + p} \right). \quad (6)$$

By replacing the value p_1 based on the measured value of differential pressure along the length of the pipe Δp_L is defined by the equation

$$p_1 = p + \Delta p_L, \quad (7)$$

we obtain the equation for calculating the average value of gas pressure along the length of the pipe

$$\bar{p} = \frac{2}{3} p \left(1 + \tau_L + \frac{1}{2 + \tau_L} \right), \quad (8)$$

where

$$\tau_L = \frac{\Delta p_L}{p}.$$

By substituting coefficient λ in equation (4) and taking into account that [10]

$$Ra = \frac{k_S}{\pi}, \quad (9)$$

we obtain the equation for measurement of Ra in real time

$$Ra = \frac{D}{\pi} (3.71 \cdot 10^{-Re_{D \cdot A}} - 18.68 \cdot A), \quad (10)$$

where A is coefficient, which is defined by the equation

$$A = \frac{\mu}{D(2 + \tau_L)} \sqrt{\frac{L(\tau_L^2 + 3\tau_L + 3)}{6\Delta p_L \bar{\rho} D}}. \quad (11)$$

Considering (2), equation (10) can be written as

$$Ra = \frac{D}{\pi} \left(3.71 \cdot 10^{-\frac{A q_m A}{\pi \mu D}} - 18.68 \cdot A \right). \quad (12)$$

3. Definition of total relative expanded uncertainty of measurement result of arithmetic mean deviation of roughness profile of pipe internal surface

According to (12) considering the equations (8) and (11) the value of Ra depends on the set of input values X

$$X \in (\Delta p_L, L, p, D, \bar{\rho}, \mu, q_m), \quad (13)$$

i. e.

$$Ra = f(X). \quad (14)$$

Total relative expanded uncertainty of measurement result of arithmetic mean deviation of roughness profile of pipe internal surface in real time is calculated by the equation [11], [12]

$$U_{Ra}^* = \sqrt{c_{\Delta p_L}^{*2} U_{\Delta p_L}^{*2} + c_L^{*2} U_L^{*2} + c_p^{*2} U_p^{*2} + c_D^{*2} U_D^{*2} + c_{\bar{\rho}}^{*2} U_{\bar{\rho}}^{*2} + c_{\mu}^{*2} U_{\mu}^{*2} + c_{q_m}^{*2} U_{q_m}^{*2}}, \quad (15)$$

where $c_{\Delta p_L}^*$ is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the differential pressure between pressure of gas on distance L upstream to primary device and pressure of gas inlet face of primary device; c_L^* is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the length of straight section L of pipe; c_p^* is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the gas pressure at the inlet face of the primary device; c_D^* is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the upstream internal pipe diameter under working conditions; $c_{\bar{\rho}}^*$ is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the average value of gas density along the length of the pipe; c_{μ}^* is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the gas dynamic viscosity under working conditions; $c_{q_m}^*$ is the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the mass gas flowrate; $U_{\Delta p_L}^*$ is the relative expanded uncertainty of measurement result of the differential pressure between pressure of gas on distance L upstream to primary device and pressure of gas inlet face of primary device; U_L^* is the relative expanded uncertainty of measurement result of the length of the straight section L of pipe; U_p^* is the relative expanded uncertainty of measurement result of the gas pressure at the inlet face of the primary device; U_D^* is the relative expanded uncertainty of measurement result of the upstream internal pipe diameter under working conditions; $U_{\bar{\rho}}^*$ is the relative expanded uncertainty of measurement result of the average value of gas density along the length of the pipe; U_{μ}^* is the relative expanded uncertainty of measurement result of the gas dynamic viscosity under working conditions; $U_{q_m}^*$ is the relative expanded uncertainty of measurement result of the mass flowrate of gas.

4. Definition of relative sensitivity coefficient of output value to input value

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to parameter i of $x_i \in X$ is determined by the equation [11]

$$c_{x_i}^* = \frac{\partial Ra}{\partial x_i} \frac{x_i}{Ra}. \quad (16)$$

From (16) the relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the differential pressure between pressure of gas on distance L upstream to primary device and pressure of gas inlet face of primary device is determined by the equation

$$c_{\Delta p_L}^* = \frac{\partial Ra}{\partial \Delta p_L} \frac{\Delta p_L}{Ra}. \quad (17)$$

Considering (2), (8), (11) and (12), equation (17) can be rewritten as

$$c_{\Delta p_L}^* = -A_c^* \left[c_{\Delta p_L}^{*\bar{p}} - \frac{2(1 + \tau_L)}{2 + \tau_L} \right], \quad (18)$$

where

$$A_c^* = \frac{DA}{2\pi Ra} \left(3.71 \frac{10^{-\text{Re} \cdot A}}{\ln 10} \text{Re} + 18.68 \right).$$

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the length of the straight section L of pipe is determined by the equation

$$c_L^* = \frac{\partial Ra}{\partial L} \frac{L}{Ra}. \quad (19)$$

Considering (2), (11) and (12), equation (19) can be rewritten as

$$c_L^* = -A_c^*. \quad (20)$$

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the gas pressure at the inlet face of the primary device is determined by the equation

$$c_p^* = \frac{\partial Ra}{\partial p} \frac{p}{Ra}. \quad (21)$$

Considering (2), (8), (11) and (12), equation (21) can be rewritten as

$$c_p^* = -A_c^* \left(c_p^{*\bar{p}} - \frac{2}{2 + \tau_L} \right). \quad (22)$$

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the upstream internal pipe diameter under working conditions is determined by the equation

$$c_D^* = \frac{\partial Ra}{\partial D} \frac{D}{Ra}. \quad (23)$$

Considering (2), (11) and (12), equation (23) can be rewritten as

$$c_D^* = 1 + 5A_c^*. \quad (24)$$

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the average value of gas density along the length of the pipe is determined by the equation

$$c_{\bar{\rho}}^* = \frac{\partial Ra}{\partial \bar{\rho}} \frac{\bar{\rho}}{Ra}. \quad (25)$$

Considering (2), (11) and (12), equation (25) can be rewritten as

$$c_{\rho}^* = A_c^* . \quad (26)$$

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the gas dynamic viscosity under working conditions is determined by the equation

$$c_{\mu}^* = \frac{\partial Ra}{\partial \mu} \frac{\mu}{Ra} . \quad (27)$$

Considering (2), (11) and (12), equation (27) can be rewritten as

$$c_{\mu}^* = -\frac{18.68DA}{Ra} . \quad (28)$$

The relative sensitivity coefficient of arithmetic mean deviation of roughness profile of pipe internal surface to the mass flowrate of gas is determined by the equation

$$c_{q_m}^* = \frac{\partial Ra}{\partial q_m} \frac{q_m}{Ra} . \quad (29)$$

Considering (2), (11) and (12), equation (29) can be rewritten as

$$c_{q_m}^* = -\frac{3.71 \text{Re} DA}{Ra \ln 10} 10^{-\text{Re} \cdot A} . \quad (30)$$

Considering (18), (20), (22), (24), (26), (28) and (30), equation (15) takes the form

$$U_{Ra}^* = \left\{ A_c^{2*} \left[c_{\Delta p_L}^{*\bar{p}} - \frac{2(1+\tau_L)}{2+\tau_L} \right]^2 U_{\Delta p_L}^{*2} + A_c^{2*} U_L^{*2} + A_c^{2*} \left(c_p^{*\bar{p}} - \frac{2}{2+\tau_L} \right)^2 U_p^{*2} + \right. \\ \left. + (1+5A_c^*)^2 U_D^{*2} + A_c^{2*} U_{\rho_L}^{*2} + \left(\frac{18.68DA}{Ra} \right)^2 U_{\mu}^{*2} + \left(\frac{3.71 \text{Re} DA}{Ra \ln 10} 10^{-\text{Re} \cdot A} \right)^2 U_{q_m}^{*2} \right\}^{0,5} . \quad (31)$$

5. Conclusion

The new equation for calculating the arithmetic mean deviation of roughness profile of pipe internal surface in real time was obtained in order to solve the problems associated with the gas flowrate measurement by means of the differential pressure flowmeters. The input values which affect on measurement the arithmetic mean deviation of roughness profile of the inner surface of the measuring pipeline in real time are determined. The equations for calculating the relative sensitivity coefficient of the arithmetic mean deviation of roughness profile of pipe internal surface to the input values were obtained. The equation of total relative expanded uncertainty of measurement result of arithmetic mean deviation of roughness profile of pipe internal surface in real time and the equations for calculating the components this total uncertainty were obtained.
